REMARKS ON BANACH SPACES OF S-COTYPE p^*

BY

DANG HUNG THANG (HANOI)

Abstract. This paper continues the investigations of [10]. There are examined relations between the class of Banach spaces of S-cotype, p, the class of Banach spaces of M-cotype p in the sense of Mouchtari [7] and the class V_n of Banach spaces defined by Tien and Weron [11].

1. Introduction. Let *E* be a Banach space with dual *E'*. *E* is said to be of stable type p ($0) if, for every sequence <math>(x_n)$ in *E* with $\sum ||x_n||^p < \infty$, $\sum x_n \theta_n^{(p)}$ converges a.s., where $\theta_n^{(p)}$ are i.i.d. symmetric *p*-stable random variables. For p = 2 stable type 2 is equivalent to type 2. *E* is said to be of cotype 2 if, for every sequence (x_n) in *E* such that $\sum x_n \theta_n^{(2)}$ converges a.s., $\sum ||x_n||^2 < \infty$. It is known that an analogous definition of stable cotype p ($0) by replacing the sequence <math>\{\theta_n^{(2)}\}$ by the sequence $\{\theta_n^{(p)}\}$ does not restrict the class of Banach spaces, since the a.s. convergence of $\sum x_n \theta_n^{(p)}$ implies that $\sum ||x_n||^p$ is finite for p < 2.

In attempting to extend the results of [1] to *p*-stable measures, Tien and Weron [11] defined a class V_p $(1 \le p < 2)$ of Banach spaces, and we have defined the notion of S-cotype p [10]. From another motivation, Mouchtari [7] has introduced the notion of M-cotype p.

Our aim is to study the relation between the class M_p of spaces of M-cotype p, the class S_p of spaces of S-cotype p and the class V_p . The main results of the paper are the inclusions $M_p \subset V_p \subset S_p \subset \bigcap_{\varepsilon>0} M_{p+\varepsilon}$ $(1 \le p < 2)$, from which we obtain the inclusion $V_p \subset V_q$ for p < q (going up phenomenon). By this phenomenon we can refer to a Banach space in the class V_p as a Banach space of V-cotype p. It is interesting to know whether the three possible notions of cotype coincide.

2. Preliminaries and notation. Let *E* be a Banach space with dual *E'*. We say that *E* is a Sazonov space if there exists a topology \mathcal{T} on *E* such that a positive definite function *f* with f(0) = 1 is \mathcal{T} -continuous iff it is a characteristic

D. H. Thang

function (ch. f.) of a probability measure on E. It has been shown [6] that every Sazonov space can be embedded into L_0 and, conversely, if a Banach space with the metric approximation property embeds in L_0 , then it is a Sazonov space. In particular, every closed subspace of $L_p(1 \le p \le 2)$ is a Sazonov space, while, for p > 2, L_p is not a Sazonov space.

For a real number p ($0) we denote by <math>X_p$ a closed subspace of L_p . $A_p(E', X_p)$ denotes the set of linear continuous operators T from E' into X_p for which the function $f(a) = \exp\{-\|Ta\|^p\}$, $a \in E'$, is the ch. f. of a probability measure on E. An operator T in $A_p(E', X_p)$ for some X_p is called a A_p -operator on E'. Let \mathcal{T}_p denote the coarsest topology on E for which all the ch. f.'s of symmetric p-stable measure are continuous. A Banach space E is said to be of M-cotype $p(0 , provided that the function <math>f: E' \to C$ is the ch. f. of a probability measure on E, if it is positive definite, \mathcal{T}_p -continuous and f(0) = 1. Equivalently, a Banach space E is of M-cotype p iff any \mathcal{T}_p -continuous linear mapping A from E' into $L_0(\Omega, P)$ is decomposable. We remind that a linear mapping A from E' into $L_0(\Omega, P)$ is said to be decomposable if there exists an E-valued random variable φ such that

$$P\{\omega: Aa(\omega) = \langle \varphi(\omega), a \rangle\} = 1 \quad \text{for all } a \in E'.$$

Mouchtari [7] has shown that M-cotype 2 spaces are exactly cotype 2 spaces and M-cotype p spaces, for some p < 1, are exactly Sazonov spaces.

Following [11] we say that a Banach space E is in the class V_p (0) if $for every symmetric p-stable measure <math>\mu$ and for every symmetric p-stable cylindrical measure ν the inequality $|1 - \hat{\nu}(a)| \le |1 - \hat{\mu}(a)|$ for all $a \in E'$ implies that ν is a Radon measure, where $\hat{\mu}(a)$ and $\hat{\nu}(a)$ are the ch. f.'s of μ and ν , respectively.

Finally, a Banach space E is said to be of S-cotype p ($0) if for every sequence <math>(x_n)$ in E and every symmetric p-stable measure μ on E the inequality

 $1 - \exp\{-\sum |\langle x_n, a \rangle|^p\} \leq 1 - \hat{\mu}(a) \quad \text{for all } a \in E'$

implies that $\sum ||x_n||^p$ is finite.

In [10] it was shown that E is of S-cotype 2 iff it is of cotype 2. A Banach space with the approximation property is of S-cotype p for p < 1 iff it is a Sazonov space.

3. Relation between spaces of *M*-cotype *p*, spaces of *S*-cotype *p* and spaces in the class V_p .

1. THEOREM. Let M_p and S_p denote the class of spaces of M-cotype p and the class of spaces of S-cotype p, respectively. Then

$$M_p \subset V_p \subset S_p \subset \bigcap_{\varepsilon > 0} M_{p+\varepsilon} \quad (1 \le p < 2).$$

Proof. (a) $M_p \subset V_p$. Let E be a Banach space of M-cotype p and suppose that μ is a symmetric p-stable measure on E, and v is a symmetric p-stable

cylindrical measure on E such that $|1-\hat{v}(a)| \leq |1-\hat{\mu}(a)|$ for all $a \in E'$. From this inequality it follows that $\hat{v}(a)$ is \mathcal{T}_p -continuous. Since E is of M-cotype $p, \hat{v}(a)$ is a ch. f. of a Radon measure on E. This shows that E belongs to the class V_p .

(b) $V_p \subset S_p$. Let E be in the class V_p and let (x_n) be a sequence in E such that

$$1 - \exp\left\{-\sum |\langle x_n, a \rangle|^p\right\} \le 1 - \hat{\mu}(a) \quad \text{for all } a \in E',$$

where μ is a symmetric *p*-stable measure on *E*.

Let v be the *p*-stable cylindrical measure with the ch. f.

$$\hat{v}(a) = \exp\{-\sum |\langle x_n, a \rangle|^p\}.$$

By the assumption that *E* belongs to $V_{\vec{p}}$, $\hat{v}(a)$ is a ch. f. of a Radon measure on *E*. From the Itô-Nisio theorem it follows that the series $\sum x_n \theta_n^{(p)}$ converges a.s. Since p < 2, we have $\sum ||x_n||^p < \infty$. Hence *E* is of *S*-cotype *p*.

(c) $S_p \subset \bigcap M_{p+\epsilon}$. We split the proof into two steps.

(i) Suppose that E is of S-cotype p ($1 \le p < 2$). Then every symmetric q-stable (q > p) measure on E is the continuous image of a symmetric q-stable measure on some Sazonov space.

Indeed, let μ be a symmetric q-stable measure on E(q > p) with the ch. f. $\hat{\mu}(a) = \exp\{-\|Ta\|^q\}$, where $T \in A_q(E', L_q)$. Because of q > p, by Theorem 2 in [7], the function $\exp\{-\|Ta\|^p\}$ is also the ch. f. of a Radon measure on E. Thus $T \in A_p(E', L_q)$. Since E is of S-cotype p by Theorem 3.3 in [10], the adjoint T': $L'_q \to E$ is p-summing. By the Pietsch factorization theorem, there exists a factorization $T^*: L'_q \xrightarrow{U} S \xrightarrow{V} E$, where S is a closed subspace of L_p , V: $S \to E$ is a linear continuous operator and U: $L'_q \to S$ is a p-summing operator.

The operator U, being p-summing, is also r-summing for $1 \le p < r < q$. Let γ_q be the canonical cylindrical q-stable measure on L'_q with the ch. f. $\exp\{-\|x\|^q\}, x \in L_q, \gamma_q$ is of the scalar order r, i.e.

$$\sup_{\|x\| \leq 1} \int_{L'_q} |\langle x, y \rangle|^r \, d\gamma_q(y) < \infty.$$

Because U is r-summing (r > 1) in view of the Schwartz radonification theorem [9], $v = U(\gamma_q)$ is a Radon measure on S. We have $\mu = T^*(\gamma_q) = V[U(\gamma_q)] = V(v)$.

 ν is a symmetric q-stable measure on S and S is a Sazonov space (since every closed subspace of L_p $(1 \le p \le 2)$ is a Sazonov space).

(ii) Suppose that every symmetric p-stable measure on a Banach space E is a continuous image of a symmetric p-stable measure on some Sazonov space. Then E is of M-cotype p.

Indeed, let A be a \mathcal{T}_p -continuous linear mapping from E' into $L_0(\Omega, P)$. Then, given $\varepsilon > 0$, there exists a Λ_p -operator T_{ε} on E' such that $||T_{\varepsilon}a|| \leq 1$ implies $||Aa||_0 < \varepsilon$, where $||\cdot||_0$ is the F-norm in $L_0(\Omega, P)$ metrizing the topology of convergence in probability.

D. H. Thang

By Lemma 5.2 in [3] we can choose a single A_p -operator T on E' satisfying the following condition:

(1.1) For every $\varepsilon > 0$ there exists a $\delta > 0$ such that $||Aa||_0 < \varepsilon$, whenever $||Ta|| < \delta$.

Let μ be a symmetric *p*-stable measure generated by *T*, i.e. $\hat{\mu}(a) = \exp\{-\|Ta\|^p\}, a \in E'$. By the assumption, there exist a Sazonov space *S*, a linear continuous operator $V: S \to E$ and a symmetric *p*-stable measure *v* on *S* such that $\mu = V(v)$. Without loss of the generality we can assume that *V* is 1-1. Let *H* be a Λ_p -operator on *S'* generating *v*, i.e. $\hat{v}(b) = \exp\{-\|Hb\|^p\}, b \in S'$. We have $\hat{\mu}(a) = V(v)(a) = \hat{v}(V^*a) = \exp\{-\|HV^*a\|^p\}$. Hence

$$||Ta|| = ||HV^*a|| \quad \text{for all } a \in E'.$$

Define a linear mapping G from $V^*(E')$ into $L_0(\Omega, P)$ by $G(V^*a) = Aa$. G is well-defined on $V^*(E')$. Indeed, if $V^*a_1 = V^*a_2$, then by (1.2) we have $||T(a_1-a_2)|| = 0$, which, together with (1.1), enables us to conclude that $||A(a_1-a_2)||_0 = 0$, i.e. $Aa_1 = Aa_2$ in $L_0(\Omega, P)$. In view of (1.1), for every $\varepsilon > 0$ there exists a $\delta > 0$ such that $||G(b)||_0 < \varepsilon$, whenever $||Hb|| < \delta$ for all $b \in V^*(E')$. In other words, G is \mathcal{T}_p -continuous on $V^*(E') \subset S'$. The linearity of G is obvious. Since $V^*(E')$ is dense in S', G admits a \mathcal{T}_p -continuous linear extension on the whole S'. Because S is of M-cotype p (every Sazonov space is of M-cotype p for all p), G is decomposed by an S-valued random variable φ , i.e. $G(b)(\omega) = \langle \varphi(\omega), b \rangle$ P-a.s. for all $b \in S'$. Hence, for all $a \in E'$, $A(a)(\omega) = G(V^*a)(\omega) = \langle \varphi(\omega), V^*a \rangle = \langle V\varphi(\omega), a \rangle$ P-a.s., which shows that A is decomposable, as desired.

Thus the proof of Theorem 1 is completed.

From Theorem 1 we derive:

2. COROLLARY. If a Banach space E belongs to the class V_p , then it also belongs to the class V_q for $1 \le p < q$.

3. COROLLARY. The space $l_s(l_t)$, where $1 \le p < t < s < q$, is in the class V_q , but not in the class V_p .

Proof. By Theorem 7 in [7], $l_s(l_t)$ is of *M*-cotype *q*, hence it is in the class V_q by Theorem 1. Assume that $l_s(l_t)$ is in the class V_p . By Proposition 8 in [7], $l_s(l_t)$ is of stable type *p*, so it imbeds in L_p by Theorem 4.5 in [10]. But this contradicts Proposition 9 in [7].

Thus, it is reasonable to refer to a Banach space in the class V_p as a Banach space of V-cotype p.

4. Concluding remarks. 1. If E is of stable type p ($1 \le p < 2$), then, by Proposition 4.8 in [10] and Theorem 1, the following statements are equivalent:

(1) E is of M-cotype p.

(2) E is of V-cotype p.

(3) E is of S-cotype p.

136

It is natural to ask

PROBLEM 1. Are the three possible notions of cotype equivalent in general?

2. Garling [2] characterized spaces of cotype 2 by the following property: a Banach space E is of cotype 2 iff every symmetric Gaussian measure on E is the continuous image of a symmetric Gaussian measure on a Hilbert space.

It is known that every Hilbert space is a Sazonov space. On the other hand, because every Sazonov space S is of cotype 2, every symmetric Gaussian measure on S is the continuous image of a symmetric Gaussian measure on a Hilbert space. Then Garling's theorem can be stated as follows:

A Banach space E is of cotype 2 iff every symmetric Gaussian measure on E is the continuous image of a symmetric Gaussian measure on a Sazonov space.

We want to extend this fact to spaces of S-cotype p.

PROBLEM 2. Is it true that a Banach space E is of S-cotype p iff every symmetric p-stable measure on E is the continuous image of a symmetric p-stable measure on a Sazonov space?

In the proof of Theorem 1 we have shown that:

1° if every symmetric *p*-stable measure on E is the continuous image of a symmetric *p*-stable measure on a Sazonov space, then E is of S-cotype p;

2° if E is of S-cotype $(p-\varepsilon)$, p > 1, then every symmetric p-stable measure on E is the continuous image of a symmetric p-stable measure on a Sazonov space.

It should be noted that if the answer to Problem 2 is positive, then the answer to Problem 1 is also positive.

Acknowledgment. I am indebted to Professor Aleksander Weron for many valuable discussions during the preparation of this paper.
