Workshop on Interactions between Model Theory and Arithmetic Dynamics
The Fields Institute, Toronto, July 25 - 29, 2016
Our aim is to find a general difference counterpart of the generic cohomology appearing in the following theorem.

**Theorem (Cline, Parshall, Scott, van der Kallen)**

1. For a fixed $n$, the groups $H^n_{\text{dis}}(G(F^d), V)$ achieve a stable value as $d \to \infty$, which is called $H^n_{\text{gen}}(G, V)$.

2. For a fixed $n$, we have

$$H^n_{\text{gen}}(G, V) \cong H^n_{\text{rat}}(G, (\text{Fr}_G^r)^*(V))$$

for sufficiently large $r$. 
Fix a base field (or ring) \( k \) and an affine group scheme \( G \) over \( k \). Then \( G \) gives a functor (of rational points)

\[
F_G : \text{Alg}_k \to \text{Groups}, \quad F_G(A) = G(A).
\]

Any \( k \)-module \( M \) also gives a functor

\[
F_M : \text{Alg}_k \to \text{Mod}_k, \quad F_M(A) = M \otimes A.
\]

We call \( M \) a **rational \( G \)-module** if there is an action of \( F_G \) on \( F_M \) by \( k \)-linear maps.
Rational Representations: Comodules

For cohomological reasons, it is convenient to express a rational $G$-module as a comodule over $k[G]$ (Hopf algebra of $G$). A $k[G]$-comodule is a pair $(M, \Delta_M : M \to M \otimes k[G])$ such that the following diagram commutes.

$$
\begin{array}{ccc}
M & \xrightarrow{\Delta_M} & M \otimes k[G] \\
\downarrow{\Delta_M} & & \downarrow{\Delta_M \otimes 1} \\
M \otimes k[G] & \xrightarrow{1 \otimes \Delta_k[G]} & M \otimes k[G] \otimes k[G]
\end{array}
$$

**Theorem (Hochshild?)**

The category of $k[G]$-comodules is equivalent to the category of rational $G$-modules. This category is Abelian with enough injectives (and not enough projectives).
Let $M$ be a rational $G$-module. The rational cohomology is defined as follows

$$H^n_{\text{rat}}(G, M) := \text{Ext}^n_G(k, M).$$

The functor $H^n_{\text{rat}}$ is the $n$-th derived functor of the functor $M \mapsto M^G$, where

$$M^G = \ker(\Delta_M - \iota_M).$$

There is also an equivalent definition of rational cohomology using cocycles, similarly to the discrete (or definable) case.
Stable Cohomology

Assume that $k = \mathbb{F}_p$.

- We have the (relative) Frobenius morphism $\text{Fr}_G : G \to G$.
- For any $G$-module $M$, we have the twisted $G$-module

\[ M^{(d)} := (\text{Fr}_G^d)^*(M) \]

and the “restriction” maps

\[ H^n_{\text{rat}}(G, M^{(d)}) \to H^n_{\text{rat}}(G, M^{(d+1)}). \]

- The stable cohomology is defined as

\[ H^n_{\text{sta}}(G, M) := \lim_{\rightarrow} H^n(G, M^{(d)}). \]
Again assume that \( k = \mathbb{F}_p \).

- For any \( d \), we have the finite group \( G(\mathbb{F}_{p^d}) \) and the homomorphism \( G(\mathbb{F}_{p^d}) \to G(\mathbb{F}_{p^{d+1}}) \). Clearly, \( M \) is also a \( k[G(\mathbb{F}_{p^d})] \)-module.

- Then we have the discrete cohomology groups \( H^n_{\text{dis}}(G(\mathbb{F}_{p^d}), M) \) and the restriction maps
  \[
  H^n_{\text{dis}}(G(\mathbb{F}_{p^{d+1}}), M) \to H^n_{\text{dis}}(G(\mathbb{F}_{p^d}), M).
  \]

- The generic cohomology is defined as
  \[
  H^n_{\text{gen}}(G, M) := \varprojlim H^n_{\text{dis}}(G(\mathbb{F}_{p^d}), M).
  \]
The theorem of Cline, Parshall, Scott, Van Der Kallen is both about the **stabilization** of the rational and the stable cohomology and about the **isomorphism** between them.

**Example**

This theorem does not hold for $G = \mathbb{G}_a$...
Our project

- Develop a cohomology theory of difference (algebraic) groups.
- Explain stable cohomology using cohomology of difference algebraic groups.
- More ambitious: stating and proving a difference version of the theorem of Cline, Parshall, Scott, van der Kallen for arbitrary difference algebraic groups, which would include the classical theorem as a special case.
Evaluate rational representation

- A rational representation $M$ of $G$ can be understood as a “compatible system” of the following situations.

**Situation for a given $k$-algebra $A$**

The group $G(A)$ acts on $M \otimes A$ by $A$-linear maps. In other words, $M \otimes A$ is an $A[G(A)]$-module.

- We want to understand each individual situation in a difference case (such a situation will be an example of a discrete difference representation). We fix a difference ring $(A, \sigma_A)$ and a difference group $(G, \sigma_G)$. We define an appropriate ring which will play the role of the ring $A[G(A)]$. 
Twisted polynomials

For any difference ring \((R, \sigma)\) (unital, not necessarily commutative), the ring of twisted polynomials is defined as

\[
R[\sigma] := \{ \sum t^i r_i \mid r_i \in R \}, \quad t^n r \cdot t^m r' := t^{n+m} \sigma^m(r)r'.
\]

Let \(M\) be a left \(R\)-module and \(\sigma_M : M \to M\) be additive. \((M, \sigma)\) is a left \(R[\sigma]\)-module if and only if:

\[
\sigma_M(\sigma(r).m) = r.\sigma_M(m)
\]

E.g. \((R, \sigma^{-1})\) is a left \(R[\sigma]\)-module (if \(\sigma^{-1}\) exists).

Right \(R[\sigma]\)-modules (e.g. \((R, \sigma)\)) correspond to the condition

\[
\sigma_M(m.r) = \sigma_M(m).\sigma(r)
\]
Discrete difference representations

- For a difference group \((G, \sigma_G)\) and a difference ring \((A, \sigma_A)\), we define the difference ring \(R := A[G]\) with
  \[
  \sigma \left( \sum \alpha_i g_i \right) := \sum \sigma_A(\alpha_i) \sigma_G(g_i).
  \]

- A **discrete difference representation** of \((G, \sigma_G)\) over \((A, \sigma_A)\) is defined as a left \(A[G][\sigma]\)-module.

- Since the category of difference discrete representations is the same as the category of left \(A[G][\sigma]\)-modules, it is Abelian with enough injectives and we define (assuming here that \(\sigma_A\) is an automorphism):
  \[
  H^n_\sigma ((G, \sigma_G), (M, \sigma_M)) := \text{Ext}^n ((A, \sigma_A^{-1}), (M, \sigma_M)).
  \]
The functor $H^n$ is the $n$-th derived functor of the functor

$$M \mapsto M^G \cap M^{\sigma M}.$$ 

We have the following spectral sequence (coming from the Grothendieck spectral sequence)

$$E_2^{n,m} = H^n(1, H^m(G, M)) \Rightarrow H^{n+m}(G, M),$$

where $1$ is the trivial group.

After an easy computation of the difference cohomology of the trivial group, this spectral sequence yields the following short exact sequence

$$0 \to H^{n-1}(G, M)_\sigma \to H^n(G, M) \to H^n(G, M)^\sigma \to 0.$$
Let us fix a base inversive difference field \((k, \sigma)\) and an affine difference algebraic group \((G, \sigma)\) (precise definition later). A rational difference \(G\)-module should satisfy the following conditions.

1. For each difference \((k, \sigma)\)-algebra \((A, \sigma_A)\), we should have a “compatible system” of discrete difference representations.

2. The category of rational difference \(G\)-modules should be Abelian with enough injectives.

3. We should have spectral sequences connecting rational difference cohomology with rational cohomology.

4. Rational difference cohomology should explain stable cohomology.
What is a difference algebraic group

- An **affine difference algebraic group** is a representable functor from the category of difference \((k, \sigma)\)-algebras to the category of groups.
- It is represented by a **difference Hopf algebra** which may be defined as \((H, \sigma_H)\), where \(H\) is a Hopf algebra over \(k\) and \(\sigma_H : \sigma^*(H) \to H\) is a Hopf algebra morphism.
- Dualizing, we see that a difference algebraic group \(G\) is the same as a pair \((G, \sigma_G)\) where \(G\) is an affine group scheme over \(k\) and \(\sigma_G : G \to \sigma^*(G)\) is a group scheme morphism.
- It fits to the general set-up from Tom’s first lecture: group objects in the category \(\sigma C\) may be identified with pairs \((G, \sigma_G)\) ... Here, the situation is a bit twisted, since we consider objects over a fixed difference object \((k, \sigma)\).
Twisted rational representations

We fix a difference algebraic group $\mathcal{G} = (\mathbf{G}, \sigma_{\mathbf{G}})$ and for simplicity we assume that $\mathbf{G}$ is defined over $\mathbf{k}^{\sigma}$. Let $(M, \sigma_M)$ be a left $\mathbf{k}[\sigma]$-module. In this “Attempt 1 case”, we have the following.

**Definition**

A **rational difference $\mathcal{G}$-module** is a pair $(M, \sigma_M)$ as above, together with a rational $\mathbf{G}$-module structure on $M$ such that

$$\sigma_M : \sigma_{\mathbf{G}}^*(M) \to M$$

is a rational $\mathbf{G}$-module morphism.

We will see that this definition satisfies the conditions (2), (3), (4). However, (to our taste) it does not satisfy the condition (1).
In the comodule terms, a rational difference $G$-module is a triple $(M, \sigma_M, \Delta_M)$ such that $(M, \Delta_M)$ is a comodule over $k[G]$ and the following diagram is commutative:

\[
\begin{array}{ccc}
M & \xrightarrow{\sigma_M} & M \\
\downarrow{\Delta_M} & & \downarrow{\Delta_M} \\
k[G] \otimes M & \xrightarrow{\sigma_k[G] \otimes \sigma_M} & k[G] \otimes M,
\end{array}
\]

where $k[G]$ is the Hopf algebra of $G$. 
Good properties

The category of rational difference $\mathcal{G}$-modules is Abelian with enough injectives so we can define in a usual way:

$$H^{n}_{\sigma \text{rat}}(\mathcal{G}, \mathcal{M}) := \text{Ext}^{n}((k, \sigma^{-1}), \mathcal{M})$$

where $\mathcal{M} = (M, \sigma_{M})$. We get a result as in the discrete case.

**Theorem (Chałupnik, K.)**

We have the following spectral sequence

$$E_{2}^{n, m} = H^{n}_{\sigma \text{rat}}(1, H^{m}_{\text{rat}}(\mathcal{G}, \mathcal{M})) \Rightarrow H^{n+m}_{\sigma \text{rat}}(\mathcal{G}, \mathcal{M})$$

and a short exact sequence

$$0 \rightarrow H^{n-1}_{\text{rat}}(\mathcal{G}, \mathcal{M})_{\sigma} \rightarrow H^{n}_{\sigma \text{rat}}(\mathcal{G}, \mathcal{M}) \rightarrow H^{n}_{\text{rat}}(\mathcal{G}, \mathcal{M})^{\sigma} \rightarrow 0.$$
Telescope and rational cohomology

To any rational $G$-module $V$, we can functorially associate the telescope difference rational $G$-module

$$V^\infty := \bigoplus_{i=0}^{\infty} (\sigma_G^i)^*(V).$$

Since $(\sigma_G)^*(V^\infty) = \bigoplus_{i=1}^{\infty} (\sigma_G^i)^*(V)$, the inclusion

$$\bigoplus_{i=1}^{\infty} (\sigma_G^i)^*(V) \subset \bigoplus_{i=0}^{\infty} (\sigma_G^i)^*(V)$$

defines on $V^\infty$ the structure of a difference rational $G$-module.

**Theorem (Chałupnik, K.)**

*We have the following isomorphism*

$$H_{\text{sta}}^{n-1}(G, V) \cong H_{\sigma \text{rat}}^n(G, V^\infty).$$
More functorial approach

This is really work in progress. For any left \( k[\sigma] \)-module \( \mathcal{M} = (M, \sigma_M) \) we define the following functor

\[
F_{\mathcal{M}} : \text{Alg}(k, \sigma) \rightarrow \text{Mod}_{k[\sigma]}, \quad F_{\mathcal{M}}(A, \sigma_A) := A[\sigma_A] \otimes_{k[\sigma]} \mathcal{M}.
\]

In this “Attempt 2 case”, we have the following.

**Definition**

We call \( \mathcal{M} \) a **difference rational** \( \mathcal{G} \)-module if there is an action of the functor \( F_{\mathcal{G}} \) on the functor \( F_{\mathcal{M}} \) by \( k[\sigma] \)-linear maps.
In this case, it is not even easy to find the right notion of a comodule map capturing this definition of a difference rational $G$-module. We have recently achieved it, the new comodule map $\Delta_M$ should fit into the following commutative diagram.
Yetter-Drinfeld modules

- The map $br$ in this diagram has some properties of the braiding map appearing in the context of Yetter-Drinfeld modules, but we do not have satisfactory understanding yet.

- We have not shown yet that the resulting category is Abelian with enough injectives (a Yetter-Drinfeld module interpretation would help).

- This “Attempt 2 notion” is different than the “Attempt 1 notion”! The second notion generalizes the first one only in the case of $\sigma_G = id_G$. 
Comparison to the other difference representation theory

- There is a theory of representations of difference algebraic groups: Ovchinnikov/Wibmer, Kamensky, ...

- Lemma 3.1.2. from Wibmer’s Habilitation “Affine Difference Algebraic Groups” amounts to saying that the category of difference representations (in their sense) of $\mathcal{G} = (G, \sigma_G)$ is equivalent to the category of rational representations of $G$. So, the cohomology groups are the same as the rational ones.

- The difference rational representations (again, in their sense) of $(G, \sigma_G)$ coincide with the difference rational representations of $(G, \text{id}_G)$, so this notion of a difference representation fits both into “Attempt 1 case” and into “Attempt 2 case”.
