Abstract. It is shown that the hyperbolic functions can be associated with selfdecomposable distributions (in short: \(SD\) probability distributions or \(Evy\) class \(L\) of probability laws). Consequently, they admit associated background driving \(\text{Lévy processes} Y\) (BDLP's \(Y\)). We interpret the distributions of \(Y(1)\) via Bessel squared processes, Bessel bridges and local times.

2000 Mathematics Subject Classification: Primary 60E07, 60E10; Secondary 60Bl1, 60G51.

Key words and phrases: Hyperbolic characteristic functions; class \(L\) or \(SD\) probability distributions; selfdecomposability; \(\text{Lévy process}\); Bessel squared process; Bessel bridge; local times.

1. INTRODUCTION AND TERMINOLOGY

The aim of this note is to provide a new way of looking at the hyperbolic functions: \(\cosh\), \(\sinh\) and \(\tanh\), or their modifications, as the members of the class \(SD\) of selfdecomposable characteristic functions (often called class \(L\), after Paul \(\text{Lévy}\)). Analytically, we say that a characteristic function \(\phi\) is selfdecomposable, and simply write \(\phi \in SD\), if

\[
\forall (0 < c < 1) \exists q_c \forall t \in R \, \phi(t) = \phi(ct) \, q_c(t),
\]

where \(q_c\) is also a characteristic function. Let us recall here that class \(SD\) is a proper subset of \(ID\), the class of all \(\text{infinitely divisible characteristic functions}\), and that the factors \(q_c\) in (1) are in \(ID\) as well; cf. Jurek and Mason (1993), Section 3.9, or Loève (1963), Section 23 (therein this class is denoted by \(R\)). We will also use the convention that a random variable \(X\) (in short: r.v. \(X\)) or its probability distribution \(\mu_X\) or its probability density \(f_X\) is selfdecomposable if the corresponding characteristic function is in the class \(SD\). Furthermore, the equation (1) describing the selfdecomposability property, in terms of an r.v.
$X$ means that
\[ X \in SD \quad \text{iff} \quad \forall (0 < c < 1) \exists \text{r.v. } X_c \quad X \overset{d}{=} cX + X_c, \]
where the r.v.'s $X$ and $X_c$ are independent and $\overset{d}{=}$ means equality in distribution.

For further references let us recall the main properties of selfdecomposable distributions (or characteristic functions or r.v.'s):

(a) SD with convolution and weak convergence forms a closed convolution subsemigroup of ID.

(b) SD is closed under affine mappings, i.e., for all reals $a$ and $b$ one has:
\[ \phi \in SD \quad \text{iff} \quad e^{ibt} \phi(at) \in SD. \]

(c) $X \in SD$ iff there exists a (unique) Lévy process $Y(\cdot)$ such that
\[ X \overset{d}{=} \int_0^\infty e^{-s} dY(s), \]
where $Y$ is called the BDLP (background driving Lévy process) of the $X$. Moreover, one has $E \left[ \log (1 + |Y(1)|) \right] < \infty$.

[ID$_{log}$ will stand for the class of all infinitely divisible laws with finite logarithmic moments.]

(d) Let $\phi$ and $\psi$ denote the characteristic functions of $X$ and $Y(1)$, respectively, in (c). Then one has
\[ \log \phi(t) = \int_0^t \log \psi(v) dv, \quad \text{i.e.,} \quad \psi(t) = \exp \left[ t (\log \phi(t))' \right], \quad t \neq 0, \quad \psi(0) = 1. \]

(e) Let $M$ be the Lévy spectral measure in the Lévy-Khintchine formula of $\phi \in SD$. Then $M$ has a density $h(x)$ such that $xh(x)$ is non-increasing on the positive and negative half-lines.

Furthermore, if $h$ is differentiable almost everywhere, then $dN(x) = -(xh(x))' dx$ is the Lévy spectral measure of $\psi$ in (d).

Finally, one has also the following logarithmic moment condition:
\[ \int_{|x| > \varepsilon} \log (1 + |x|) dN(x) < \infty \quad \text{for all positive } \varepsilon. \]

Parts (a) and (b) follow directly from (1). For (c) and (d) cf. Jurek and Mason (1993), Theorem 3.6.8 and Remark 3.6.9 (4). Part (e) is Corollary 1.1 from Jurek (1997).

In this note we will characterize the BDLP's (or the characteristic functions $\psi$ in (d)) for the hyperbolic characteristic functions. The main result shows how to interpret these distributions in terms of squared Bessel bridges (Corollary 2) and squared Bessel processes (Corollary 3).
2. SELFDECOMPOSABILITY OF THE HYPERBOLIC CHARACTERISTIC FUNCTIONS

For this presentation the most crucial example of SD r.v. is that of the \textit{Laplace} (or double exponential) random variable $\eta$. So, $\eta$ has the probability density $\frac{1}{2}e^{-|x|}$, $x \in \mathbb{R}$, and its characteristic function is equal to

$$
\phi_\eta(t) = \frac{1}{1+t^2} = \exp \left[ \int_{-\infty}^{\infty} \frac{e^{itx}-1}{|x|} \, dx \right] = \exp \left[ \int_{0}^{t} \int_{-\infty}^{\infty} (e^{ix} - 1) e^{-|x|} \, dx \right] \frac{dv}{v} \in SD.
$$

To see its selfdecomposability property simply note that

$$
\phi_\eta(t) = \frac{1+c^2 t^2}{1+t^2} = c^2 1 + (1-c^2) \frac{1}{1+t^2}
$$

is the characteristic function of $\eta_c$ in the formula (1). The rest follows from appropriate integrations; cf. Jurek (1996).

Another, more “stochastic” argument for selfdecomposability of the Laplace r.v. $\eta$, as a counterpart of the above analytic one, is as follows.

Firstly, notice that for three independent r.v.'s $\varepsilon(1)$, $\tilde{\varepsilon}(1)$ and $b_c$, where the first two have exponential distribution with parameter 1 and the third one has Bernoulli distribution ($P(b_c = 1) = 1 - c$ and $P(b_c = 0) = c$), we obtain the equality

$$
\varepsilon(1) \overset{d}{=} c \varepsilon(1) + b_c \tilde{\varepsilon}(1),
$$

which means that $\varepsilon(1)$ is a selfdecomposable r.v. (The above distributional equality is easily checked by using the Laplace or Fourier transform.)

Secondly, taking two independent Brownian motions $B_t$, $\tilde{B}_t$, $t \geq 0$, and independently of them an exponential r.v. $\varepsilon(1)$ satisfying the above decomposition, we infer that

$$
B_{\varepsilon(1)} \overset{d}{=} \sqrt{c} B_{\varepsilon(1)} + \tilde{B}_{b_c \varepsilon(1)},
$$

and thus proving that stopped Brownian motion $B_{\varepsilon(1)}$ is selfdecomposable as well.

Thirdly, let us note that $B_{\varepsilon(1)}$ has the double exponential distribution. More explicitly we have

$$
E \left[ \exp \left( \sqrt{2} B_{\varepsilon(1)} \right) \right] = E \left[ \exp \left( -t^2 \varepsilon(1) \right) \right] = \frac{1}{1+t^2} = \phi_\eta(t).
$$

PROPOSITION 1. The following three hyperbolic functions: $1/cosh t$, $t/sinh t$, $(\tanh t)/t$, $t \in \mathbb{R}$, are characteristic functions of selfdecomposable probability distributions, i.e., they are in the class $SD$.

Proof. From the following product representations:

$$
cosh z = \prod_{k=1}^{\infty} \left( 1 + \frac{4z^2}{(2k-1)^2 \pi^2} \right), \quad sinh z = z \prod_{k=1}^{\infty} \left( 1 + \frac{z^2}{k^2 \pi^2} \right)
$$

for all complex $z$, and from (2) with (a) we conclude that the first two hyperbolic functions are characteristic functions from $SD$. Moreover, these are characteristic functions of the series of independent Laplace r.v.'s; cf. Jurek (1996).

Note that for $0 < a < b$ the fraction

$$\frac{1 + a^2 t^2}{1 + b^2 t^2} = \frac{a^2}{b^2} 1 + \left(1 - \frac{a^2}{b^2}\right) \frac{1}{1 + b^2 t^2}
$$

is a characteristic function, and so is

$$\frac{\tanh t}{t} = \prod_{k=1}^{\infty} \frac{1 + (k\pi)^{-2} t^2}{1 + ((k-\frac{1}{2})\pi)^{-2} t^2}
$$

as a converging infinite series of characteristic functions of the above form. Its selfdecomposability follows from Yor (1997), p. 133, or Jurek (2001), Example 1 (b).

Remark 1. The selfdecomposability of $(\tanh t)/t$, i.e., the formula (1), would follow in an elementary manner if for all $0 < c < 1$ and all $0 < w < u$ the functions

$$\frac{1 + (c^2 w + u) t^2 + c^2 u w t^4}{1 + (u + c^2 w) t^2 + c^2 u w t^4} = \frac{1 + w t^2 + c^2 u t^2}{1 + u t^2 + c^2 w t^2}
$$

were characteristic functions. [The above is a ratio of two fractions of the form as in the product representation of $(\tanh t)/t$ with fraction in the denominator computed at $ct$.] However, they cannot be characteristic functions! The affirmative answer would mean that the Laplace r.v. is in $L_1$. (These are those $SD$ r.v.'s for which $BDLP \ Y(1)$ in (c) is $SD$. Equivalently, the characteristic function $\varphi_e$ in (1) is in $SD$.) But from (2) we see that $Y(1)$ for the Laplace r.v. $\eta$ has compound Poisson distribution with Lévy spectral measure $dM(x) = e^{-|x|} dx$ which does not satisfy the criterium (e). Cf. also Jurek (1997).

3. THE BDLP's OF THE HYPERBOLIC CHARACTERISTIC FUNCTIONS

Since the three hyperbolic characteristic functions are infinitely divisible, one can insert them into Lévy processes: $\tilde{C}_s$, $\tilde{S}_s$, $\tilde{T}_s$, for $s \geq 0$, corresponding to cosh, sinh and tanh characteristic functions. Those processes were studied from
Selfdecomposable laws associated with hyperbolic functions

185

the ID class point of view in the recent paper by Pitman and Yor (2003). Here we are looking at them from the SD class point of view, i.e., via the corresponding BDLP’s.

In the sequel, φ with subscript Ċ, Š or Ĩ denotes one of the three hyperbolic characteristic functions, M with those subscripts denotes the Lévy spectral measure in the appropriate Lévy–Khintchine formula; furthermore, ψ with the above subscripts is the corresponding characteristic function in the random integral representation (properties (c) and (d) of class SD), and finally N with one of the above subscripts is the Lévy spectral measure of ψ (as in (e)). Thus we have the equalities:

$$
\phi_{\check{C}}(t) = \phi_{\check{S}}(t) \cdot \phi_{\check{T}}(t), \quad \text{i.e.,} \quad \frac{1}{\cosh t} = \frac{t}{\sinh t} \cdot \frac{\tanh t}{t},
$$

(4)

$$
M_{\check{C}}(\cdot) = M_{\check{S}}(\cdot) + M_{\check{T}}(\cdot), \quad \text{where} \quad \frac{dM_{\check{C}}(x)}{dx} = \frac{1}{2x \sinh (\pi x/2)};
$$

$$
\frac{dM_{\check{S}}(x)}{dx} = \frac{e^{-\pi|x|/2}}{2x \sinh (\pi x/2)} = \frac{1}{2|x|} \left( \coth \left( \frac{\pi |x|}{2} \right) - 1 \right),
$$

(5)

$$
\frac{dM_{\check{T}}(x)}{dx} = \frac{1}{2|x|} \frac{e^{-\pi|x|/4}}{\cosh (\pi |x|/4)} = \frac{1}{2|x|} \left[ 1 - \tanh (\pi |x|/4) \right].
$$

These are consequences of the appropriate Lévy–Khintchine formulas for the hyperbolic characteristic functions or see Jurek (1996) or Pitman and Yor (2003) or use (2) and the product formulas for cosh z, sinh z (for tanh z use the ratio of the previous two formulas).

**Corollary 1.** For the SD hyperbolic characteristic functions φ_{\check{C}}, φ_{\check{S}} and φ_{\check{T}}, their background driving characteristic functions are ψ_{\check{C}}, ψ_{\check{S}} and ψ_{\check{T}}, where

$$
\psi_{\check{C}}(t) = \psi_{\check{S}}(t) \cdot \psi_{\check{T}}(t);
$$

(6)

$$
\psi_{\check{C}}(t) = \exp \left[ -t \tanh t \right], \quad \psi_{\check{S}}(t) = \exp \left[ 1 - t \coth t \right],
$$

$$
\psi_{\check{T}}(t) = \exp \left[ \frac{1}{\cosh t} \cdot \frac{t}{\sinh t} - 1 \right] = \exp \left[ \frac{2t}{\sinh (2t)} - 1 \right].
$$

Probability distributions corresponding to ψ_{\check{C}}, ψ_{\check{S}} and ψ_{\check{T}} are infinitely divisible with finite logarithmic moments.

Proofs follow from (4) and the properties (c) and (d) of the selfdecomposable distributions.

Let us note that ψ_{\check{T}} is the characteristic function of the compound Poisson distribution with summand being the sum of independent r.v.’s with cosh and sinh characteristic functions.
Finally, on the level of the Lévy measures $N$ of $Y(1)$, from the BDLP's in the property (e), we have the following:

$$N_C(\cdot) = N_S(\cdot) + N_T(\cdot),$$

where

$$\frac{dN_C(x)}{dx} = \frac{\pi \cosh(\pi x/2)}{4 \sinh^2(\pi x/2)},$$

$$\frac{dN_S(x)}{dx} = \frac{\pi}{4 \sinh^2(\pi x/2)},$$

$$\frac{dN_T(x)}{dx} = \frac{\pi}{8 \cosh^2(\pi x/4)}.$$

Explicitly, as in (4), on the level of the BDRV we have the factorization

$$\exp[-t \tanh t] = \exp[1 - t \coth t] \cdot \exp\left[\frac{t}{\cosh t \sinh t} - 1\right].$$

Taking into account all the above and the property (e) we arrive at the identities:

$$\int_{R\setminus\{0\}} (1 - \cos tx) \frac{\pi \cosh(\pi x/2)}{4 \sinh^2(\pi x/2)} dx = t \tanh t,$$

$$\int_{R\setminus\{0\}} (1 - \cos tx) \frac{\pi}{4 \sinh^2(\pi x/2)} dx = t \coth t - 1,$$

$$\int_{R\setminus\{0\}} (1 - \cos tx) \frac{\pi}{8 \cosh^2(\pi x/4)} dx = 1 - \frac{2t}{\sinh 2t}.$$

Furthermore, since $\psi_T$ corresponds to a compound Poisson distribution, the last equality implies that

$$\int_{R\setminus\{0\}} \cos tx \left[\frac{\pi}{8 \cosh^2(\pi x/4)} \right] dx = \frac{2t}{\sinh 2t},$$

where we recover the known relation between $(\cosh u)^{-2}$ being the probability density corresponding to the characteristic function $at/(\sinh at)$ and vice versa by the inversion formula; cf. Lévy (1951) or Pitman and Yor (2003), Table 6.

4. STOCHASTIC INTERPRETATION OF BDLP's FOR HYPERBOLIC FUNCTIONS

The functions $\psi_C(t)$ and $\psi_S(t)$ were identified as characteristic functions of the background driving random variable $Y(1)$ (in short: BDRV) for cosh and sinh SD r.v.'s in Jurek (1996), p. 182. [By the way, the question raised there has an affirmative answer. More precisely: (23) implies (24). To see this note that $D_1 \overset{d}{=} \frac{1}{2} \mathcal{D}_1 + C$, where $\mathcal{D}_1$ is a copy of $D_1$ and is independent of $C$. The notation here is from the paper in question.]
More recently, in Jurek (2001) it was noticed that the conditional characteristic function of the Lévy stochastic area integral is a product of the sinh characteristic function and its BDLP $\psi_g$. A similar factorization is in the Wenocur formula; see Wenocur (1986). Cf. also Yor (1992a), p. 19.

In this section we give some "stochastic" interpretation of the characteristic functions $\psi_C(t)$ and $\psi_S(t)$ in terms of Bessel processes.

Let us recall here some basic facts and notation from Pitman and Yor (1982) and Yor (1992a), (1997). Cf. also Revuz and Yor (1999).

For the $\delta$-dimensional Brownian motion ($B_t, t \geq 0$), starting from a vector $a$, we define the process $X_t = |B_t|^2, t \geq 0$, which in turn defines the probability distribution (law) $Q^\delta_x, x := |a|^2$, on the canonical space $\mathcal{Q} := C([0, \infty); [0, \infty])$ of non-negative functions defined on the half-line $[0, \infty)$, equipped with the $\sigma$-field $\mathcal{F}$ such that mappings $\{\omega \mapsto X_s(\omega)\}$ are measurable. In fact, $(X_t, t \geq 0)$ is the unique strong solution of a stochastic integral equation

$$X_t = x + 2 \int_0^t \sqrt{X_s} \, d\beta_s + \delta t, \quad t \geq 0,$$

where $(\beta_t, t \geq 0)$ is a 1-dimensional Brownian motion.

The laws $Q^\delta_x$ satisfy the following convolution equation due to Shiga–Watanabe:

$$Q^\delta_x * Q^\delta_y = Q^\delta_{x+y} \quad \text{for all } \delta, \delta', x, x' \geq 0,$$

where, for $P$ and $Q$ being two probabilities on $(\Omega, \mathcal{F})$, $P * Q$ denotes the distribution of $(X_t, t \geq 0)$, with $(X_t, t \geq 0)$ and $(Y_t, t \geq 0)$ being two independent processes, respectively, $P$- and $Q$-distributed; cf. Revuz and Yor (1999), Chapter XI, Theorem 1.2.

Similarly, let $Q^\delta_{s \rightarrow y}$ be a $\delta$-dimensional squared Bessel bridge of $(X_s, 0 \leq s \leq 1)$, given $X_1 = y$, viewed as a probability on $C([0, 1], [0, \infty])$.

In the sequel we use integrals of functionals $F$ with respect to measures $Q$ over function spaces. To simplify our notation, as in Revuz and Yor (1999), we use $Q(F)$ to denote such integrals. From Yor (1992a), Chapter 2, the Lévy stochastic area formula is given in the form

$$Q^\delta_{s \rightarrow 0} \left[ \exp \left( -\frac{\lambda^2}{2} \int_0^s dsX_s \right) \right] = \left( \frac{\lambda}{\sinh \lambda} \right)^{d/2} \exp \left( -\frac{x}{2} (\lambda \coth \lambda - 1) \right).$$

However, since $Q^\delta_{s \rightarrow 0} = Q^0_{0 \rightarrow 0} * Q^\delta_{s \rightarrow 0}$ (cf. Yor (1992), Pitman and Yor (1982)), we have in fact

$$Q^0_{x \rightarrow 0} \left( \exp \left( -\frac{\lambda^2}{2} \int_0^s dsX_s \right) \right) = \exp \left( -\frac{x}{2} (\lambda \coth \lambda - 1) \right).$$
Thus we may conclude the following.

**Corollary 2.** The BDLP \( Y \), for the SD characteristic function \( \phi_S(t) = t/(\sinh t) \), is such that \( Y(1) \) has the characteristic function

\[
\psi_S(t) = \exp(1 - t \coth t) = Q_2^{t\rightarrow 0} \exp(it\gamma(t;\mathcal{L}X_a)) \in ID_{\log},
\]

where \((\gamma, s \geq 0)\) is a Brownian motion independent of the Bessel squared process \( X \).

[Here it may be necessary to enlarge the probability space to support independent \( \gamma \) and \( X \).]

In a similar way, in view of Yor (1992a), Chapter 2, we have

\[
Q_2^0 \left( \exp \left( -\frac{\lambda^2}{2} \int_0^1 dsX_s \right) \right) = \left( \frac{1}{\cosh \lambda} \right)^{\lambda/2} \exp \left( -\frac{x}{2} \lambda \tanh \lambda \right),
\]

so, in particular,

\[
Q_2^0 \left( \exp \left( -\frac{\lambda^2}{2} \int_0^1 dsX_s \right) \right) = \exp \left( -\frac{x}{2} \lambda \tanh \lambda \right).
\]

Thus, as above, we conclude the following:

**Corollary 3.** The BDLP \( Y \), for the SD characteristic function \( \phi_C(t) = 1/(\cosh t) \), is such that \( Y(1) \) has the characteristic function

\[
\psi_C(t) = \exp(-t \tanh t) = Q_2^0 \exp(it\gamma(t;\mathcal{L}X_a)) \in ID_{\log},
\]

where a process \((\gamma, s \geq 0)\) is a Brownian motion independent of the Bessel squared process \( X \).

Let us return again to functions \( \psi_C(t) \) and \( \psi_S(t) \), given in (6), but viewed this time as Laplace transforms in \( t^2/2 \). From Yor (1997), p. 132, we have

\[
\frac{1}{\cosh \tau} = E \left[ \exp \left( \frac{-t^2}{2} T_1^{(1)} \right) \right], \quad \frac{t}{\sinh \tau} = E \left[ \exp \left( \frac{-t^2}{2} T_1^{(3)} \right) \right],
\]

where \( T_1^{(\delta)} := \inf \{ t : \mathcal{R}_t^{(\delta)} = 1 \} \) denotes the hitting time of 1 by \( \delta \)-dimensional Bessel process \( \mathcal{R}_t^{(\delta)} \), \( t \geq 0 \), starting from zero. Jeanblanc et al. (2002), Theorem 3, found that the corresponding BDLP's \( Y \) are of the form

\[
Y(h) = \int_0^h du \mathbbm{1}_{(\mathcal{R}_u^{(\delta)} \leq 1)}, \quad h \geq 0,
\]

where \((\tau_\alpha^h, h \geq 0)\) is the inverse of the local time of \( \mathcal{R}_u^{(\delta)} \) at \( r \); cf. Revuz and Yor (1999), Chapter VI, for all needed notation and definitions. From the above we
also recover the formulae

\[
E \left[ \exp \left( -\frac{\lambda^2}{2} \int_0^t dV_1 \mathbb{1}_{|V_1| \leq 1} \right) \right] = \exp (-\lambda \tanh \lambda),
\]

(19)

\[
E \left[ \exp \left( -\frac{\lambda^2}{2} \int_0^t dV_3 \mathbb{1}_{|V_3| \leq 1} \right) \right] = \exp (-\lambda (\coth \lambda - 1)).
\]

These as well provide another “stochastic view” of the analytic formulae for the BDRV of two SD hyperbolic characteristic functions in (4), i.e., \(1/\cosh t\) and \(t/\sinh t\).
